Measuring Adoption & Acceptance via Copilot Metrics API

Question: An engineering director wants to export daily aggregated data on active Copilot Chat users, inline code suggestion acceptance counts, and breakdowns by programming language and IDE editor into an internal BI dashboard. Which GitHub capability provides this telemetry programmatically?

A. GitHub Dependabot Security Alerts REST API

B. GitHub Copilot Metrics REST API (`/orgs/{org}/copilot/metrics`) **[CORRECT ANSWER]**

C. GitHub Actions Workflow Run Logs

D. Individual developer `.git/logs` commit hooks

Explanation & Exam Rationale

The **GitHub Copilot Metrics API** provides organization and enterprise administrators with daily aggregated usage telemetry—including total active users, engaged users, inline code suggestions shown vs. accepted, lines suggested vs. accepted, and Copilot Chat turn counts segmented by editor and programming language.

Metric Dimension	What It Measures	Productivity Caveat
Active vs. Engaged Users	License seat activity vs. developers actively interacting with Copilot	Helps identify unused seats for license reallocation
Acceptance Rate	Ratio of accepted completions to total completions shown	High acceptance does not automatically prove higher code quality
Language & Editor Breakdown	Adoption patterns across Python, TypeScript, VS Code, JetBrains, etc.	Highlights teams needing targeted onboarding or training
Holistic Outcomes (SPACE / DORA)	PR cycle time, review throughput, and developer satisfaction	Must be paired with Copilot metrics to measure true engineering ROI

Key Exam Takeaway: The Copilot Metrics API requires a minimum threshold of active users (typically 5 or more) to preserve individual developer privacy and should be combined with DORA/SPACE metrics rather than relying solely on raw lines-of-code acceptance.
