Public Code Matching & Duplication Detection Filter

Question: Your legal team wants to ensure developers do not inadvertently insert verbatim snippets of open-source code exceeding roughly 150 characters from public GitHub repositories. What happens when the "Suggestions matching public code" policy is set to **Block** at the organization level?

A. Copilot displays the matching code along with an automatic SPDX license header in the editor.

B. Copilot scans the developer's local repository and deletes any files containing open-source code.

C. Suggestions matching public GitHub code of approximately 150 characters or more are suppressed before reaching the developer's IDE. **[CORRECT ANSWER]**

D. Individual organization members can override the organization's Block policy in their personal GitHub settings.

Explanation & Exam Rationale

GitHub Copilot includes a real-time duplication detection filter that compares generated completions (along with surrounding context) against an index of public code on GitHub. When an organization or enterprise administrator sets **Suggestions matching public code** to **Block**, any suggestion matching public code of roughly 150 characters or longer is discarded on the server side.

Policy Setting	Resulting Copilot Behavior	Code Referencing Feature
Block	Matching suggestions (~150+ chars) are suppressed and never shown.	Not triggered (suggestion is filtered out).
Allow	Matching suggestions are displayed normally to the developer.	Logs matching repository URLs and license types in the Copilot log / Chat citations.
Unconfigured (Org)	Defers to each user's personal GitHub Copilot setting.	Depends on individual user preference.

Key Exam Takeaway: Know the threshold (~150 characters) and remember that when set to **Allow**, GitHub Copilot's *Code Referencing* feature surfaces the source repository and license metadata so developers can make informed attribution decisions.
