Question 55

03: Understand Data & Architecture

Where are the underlying AI models powering GitHub Copilot hosted and executed when processing developer prompts?

A. Locally inside the developer's IDE extension container.

✔ **B. On Microsoft Azure cloud infrastructure managed under GitHub's enterprise security and compliance controls.**

C. On public peer-to-peer compute nodes contributed by open-source users.

D. Directly inside each organization's on-premises Git server.

Correct Answer: B

GitHub Copilot's inference service runs on **Microsoft Azure** cloud infrastructure, leveraging enterprise-grade encryption in transit (TLS) and strict tenant isolation to process prompts securely.

Option Breakdown

- **A. Locally inside IDE extension:** Incorrect. The IDE extension gathers local context and transmits encrypted prompts to cloud endpoints.
- **B. Microsoft Azure cloud infrastructure:** Correct. Provides scalable GPU inference backed by Microsoft/GitHub compliance commitments.
- **C. Public peer-to-peer nodes:** Incorrect. Copilot never distributes proprietary prompts across untrusted peer networks.
- **D. On-premises Git server:** Incorrect. Even for GitHub Enterprise Server (GHES) customers, Copilot inference connects to GitHub's cloud service.

💡 **GH-300 Exam Tip**
All prompts and suggestions are encrypted in transit using **HTTPS / TLS** between the IDE extension, GitHub's proxy service, and the Azure-hosted AI models.
